Evolutionary Games

Evolutionary Games

Consider the following evolutionary game model consisting of :

- Several class of players $\mathcal{E} = \{1, 2, \dots\}$.
- A *large* number of players (to guarantee non-atomicity),
- Many local and simultaneous interactions between some (possibility random number) of players.
- Each local interaction is described as follows:
 - region or resource called *primary action* ($r \in \mathcal{R}$)
 - each player of each class have a finite set of *secondary actions*

$$\mathcal{A}_e = \{(r, a) \mid r \in \mathcal{R}, a \in \mathcal{A}_e^r\}, X_e^r = \Delta_{m_e^r}(\mathcal{A}_e^r)$$

where \mathcal{A}_e^r is the secondary actions in region r for e .

- a payoff (reward,fitness) function:

$$F_e : \prod_{e \in \mathcal{E}} \prod_{r \in \mathcal{R}} X_e^r \longrightarrow \mathbb{R}^{|\mathcal{A}_e|}, \quad F_e(x) = (F_{e,a}^r(x))_{r,a}.$$

- the system evolves under some evolutionary game

Hamidou Tembine

Outline

The Model

migration
ESS
CCE
hybrid dynamics
Replicator

class of games
potential games
stable games

Power control

Multihoming

extensive

conclusions

- *migration*: If a player changes its actions from region r to \bar{r} (physically at the same)) or moves from r to \bar{r} (mobility), we say that player migrates from r to \bar{r} .
- *migration constraints*: we assume that player from class e in region r can migrate only in the "neighboring regions" $\mathcal{N}_{e,(r,a)} \subseteq \bigcup_r \{\{r\} \times A_e^r\}$ in one-hop.
- the neighborhood set $\mathcal{N}_{e,(r,a)}$ have the property that:

$$(\bar{r}, b) \in \mathcal{N}_{e,(r,a)} \iff (r, a) \in \mathcal{N}_{e,(\bar{r},b)}$$

Examples of migration/mobility constraints

The Model

migration

ESS

CCE

hybrid dynamics

Replicator

class of games

potential games

stable games

Power control

Multihoming

extensive

conclusions

- *Unidirectional constraint*: the player can change only one of the two components of strategy.

$$\mathcal{N}_{e,(r,a)} = (R \times \{a\}) \cup A_e^r$$

- $\mathcal{N}_{e,(r,a)} = R \times A_e$ (free migration).
- $\mathcal{N}_{e,(r,a)} = A_e^r$ (standard, no migration).

conclusions

ESS: Evolutionary Stable Strategy (Maynard Smith & Price, 1973).

Definition

(*GESS*) A strategy x is global evolutionary stable if for every strategy $mut \neq x$, there exists $\epsilon_{mut} > 0$ such that

$$\forall e, \sum_r \sum_a (x_{e,a}^r - mut_{e,a}^r) F_{e,a}^r(\epsilon mut + (1 - \epsilon)x) > 0, \forall \epsilon \in (0, \epsilon_{mut})$$

Robustness, refinement and equilibrium selection: ESS \implies proper equilibrium(Myerson), Nash equilibrium, the converse is not always true. See Maynard Smith(1982), Weibull(1995), Hofbauer & Sigmund(1998).

Choice constrained equilibrium

Evolutionary
game
dynamics with
migration

Hamidou
Tembine

Outline

The Model

migration
ESS
CCE
hybrid dynamics
Replicator

class of games
potential games
stable games

Power control

Multihoming

extensive

conclusions

A strategy x is a *choice constrained equilibrium* (CCE) if for all e, r and a such that $x_{e,a}^r > 0$ one has,

$$F_{e,a}^r(x) = \max_{(\bar{r}, b) \in \mathcal{N}_{e,(r,a)}} F_{e,b}^{\bar{r}}(x)$$

This corresponds to "local equilibrium" under migration constraints. If $x_{e,a}^r = 0$, we say that (r, a) is not used in class e .

Evolutionary Game Dynamics with migration

Let $\beta_{e,(r,a)}^{(\bar{r},b)}(\cdot)$ be a rule of actions' choice called *revision protocol* (Sandholm,2007). β depends on state of all the population and the payoffs. $\beta_{e,(r,a)}^{(\bar{r},b)}$ conditional switch rate from the secondary action b in region \bar{r} to the secondary action a in region r .

Inflow the action (r, a) of class e

$$\sum_{(\bar{r},b)} x_{e,b}^{\bar{r}} \beta_{e,(r,a)}^{(\bar{r},b)}(x, F(x))$$

Outflow of the action (r, a) of class e :

$$x_{e,a}^r \sum_{(\bar{r},b)} \beta_{e,(\bar{r},b)}^{(r,a)}(x, F(x))$$

Let

$$V_{e,F}^{(r,a)}(x) = \sum_{(\bar{r},b)} x_{e,b}^{\bar{r}} \beta_{e,(r,a)}^{(\bar{r},b)}(x, F(x)) - x_{e,a}^r \sum_{(\bar{r},b)} \beta_{e,(\bar{r},b)}^{(r,a)}(x, F(x))$$

Assume that the revision protocol satisfies

$$\beta_{e,(\bar{r},b)}^{(r,a)}(x, F(x)) > 0 \implies (\bar{r}, b) \in \mathcal{N}_{e,(r,a)}.$$

The game dynamics is then given by

$$\frac{d}{dt} x_{e,a}^r(t) = V_{e,F}^{(r,a)}(x(t)).$$

Evolutionary game dynamics with migration: examples

conclusions

- Replicator dynamics (Taylor & Jonker, 1978)

$$\beta_{e,(r,a)}^{(\bar{r},b)} = x_{e,a}^r \max(0, F_{e,a}^r - F_{e,b}^{\bar{r}})$$

- Brown-von Neumann-Nash (BNN)(1950) dynamics

$$\beta_{e,(r,a)}^{(\bar{r},b)} = \max(0, F_{e,a}^r - \sum_{(\bar{r},b)} x_{e,b}^r F_{e,b}^{\bar{r}})$$

- Smith dynamics $\beta_{e,(r,a)}^{(\bar{r},b)} = \max(0, F_{e,a}^r - F_{e,b}^{\bar{r}})$

Other dynamics: fictitious play, gradient, projection, differential inclusion, best response BR:

$$BR_e(x) = \arg \max_y \{ \sum_{(r,a)} y_{e,a}^r F_{e,a}^r(x) \}. \text{ BR dynamics: } \dot{x}_e \in BR_e(x) - x_e$$

Folk theorem (evolutionary version): Every GNE is a stationary of the theses dynamics (in particular for GESS).
Every stationary point of BNN, BR or Smith dynamics is GNE of the local game.

Outline

The Model

migration

ESS

CCE

hybrid dynamics

Replicator

class of games

potential games

stable games

Power control

Multihoming

extensive

conclusions

$$x_{e,a}^r(t+\Delta t) = x_{e,a}^r(t) \frac{1 - \Delta_e t + \Delta_e t[\delta_e + F_{e,a}^r(x(t))]}{1 - \Delta_e t + \Delta_e t[\delta_e + \sum_{(r,a)} x_{e,a}^r(t) F_{e,a}^r(x(t))]}$$

Note that when $\Delta_e t$ goes to zero, we obtain the continuous time RD.

Discrete Time Replicator Dynamics

$$x_{e,a}^r(t+1) = x_{e,a}^r(t) \frac{\delta_e + F_{e,a}^r(x(t))}{\delta_e + \sum_{(\bar{r},b) \in \mathcal{N}_{e,(r,a)}} x_{e,b}^{\bar{r}}(t) F_{e,b}^{\bar{r}}(x(t))}$$

Every equilibrium of the game is a fixed point of (DRD).

- Positive Correlation (PC):

$$V_F(x) \neq 0 \implies \sum_{e,r,a} \left[\frac{d}{dt} x_{e,a}^r \right] F_{e,a}^r(x) > 0.$$

Under (PC), every CCE is rest point of the dynamics.

- Constrained Nash stationarity (CNS): The rest points of the dynamics are exactly the CCEs of the evolutionary game.

Result

RD, BNN, Smith dynamics satisfy (PC). Moreover, BNN and Smith dynamics satisfy (CNS).

stable games

Power control

Multihoming

extensive

conclusions

Result

Global convergence holds in potential games under (PC)

Some elements: let f be a C^1 function such that

$$\nabla f = F$$

then,

$$\frac{d}{dt}f(x(t)) = \sum_e \sum_r \sum_a V_{e,F}^{(r,a)}(x(t)) F_{e,a}^r(x(t))$$

and Lyapunov's theorem completes the proof.

Simple class of dynamics

Result

Every GNE is GNESS in stable games. The set of CCE is asymptotically globally stable in stable games under the dynamics generated by

$$\beta_{e,(r,a)}^{(\bar{r},b)}(x) = \mu_e^r \max\{0, F_{e,a}^r(x) - F_{e,b}^{\bar{r}}(x)\}^\theta,$$

if $(\bar{r}, b) \in \mathcal{N}_{e,(r,a)}$ and 0 otherwise. μ_e^r is growth parameter.

Proof:

$$B(x) = \frac{1}{1+\theta} \sum_{e=1}^E \sum_{(r,a)} \sum_{(\bar{r},b)} \mu_e^r x_{e,a}^r \max\{0, F_{e,a}^r(x) - F_{e,b}^{\bar{r}}(x)\}^{1+\theta}$$

- the zeros of B are CCEs.
- since ${}^t\dot{x}D_x F\dot{x} \leq 0$, $\frac{d}{dt}B(x) \leq 0$

Concave function (recall)

$f : \mathbb{R}^n \rightarrow \mathbb{R}$ C^1 concave function

- then f satisfies

$$\langle \nabla_y f, x - y \rangle \geq f(x) - f(y)$$

Swap x and y and sum:

$$\langle \nabla_x f, y - x \rangle \geq f(y) - f(x)$$

$$\langle x - y, -\nabla_x f + \nabla_y f \rangle \geq 0$$

$$\langle x - y, \nabla_x f - \nabla_y f \rangle \leq 0$$

link with Rosen's(1965) condition
